

All Git commands and GitHub

~\$git init

> To initialise the directory for git

~\$git add .

> To add code to staging area(Tracked files)

~\$git config --global [user.name](#) "GitHub username"

> To configure username of GitHub for pushing/committing code

~\$git config --global [user.email](#) "your GitHub email"

> To configure GitHub email

~\$git commit -m "commit message"

> To commit the changes to local repo

~\$git push origin branchname

enter username and then

Token

> To push code to GitHub

~\$git branch

> To check all the branches and your current branch

~\$git branch "branchname"

> To create a new branch

~\$git checkout "branchname"

> To switch to that branch

~\$git checkout -b "branchname"

> To create a new branch and switch on it

~\$git branch -d "branchname"

> To delete branch

~\$git log

> To check all commits done in the past

~\$git show or git show (commit Id)

> To check commit details

~\$git remote -v

> To check which repository is configured

~\$git remote add origin <RepoURL>

> To configure GitHub repository

~\$git reset

> To remove changes done to staging area

~\$git reset --hard

> To remove all the changes done

~\$git revert

> To remove the commit

~\$git stash

> To stash ongoing work file (Will be ignored for adding to staging area)

~\$git clone <GitHub URL>

> To clone GitHub repository

~\$git pull origin branchname/master

> To pull code to your server

~\$git remote set-url origin <GitHub URL>

> To set other repository as origin (If already present only)

~\$git status

> To check tracked and untracked files

Push code to GitHub and merge

Go to Chrome

Create a GitHub account

Create a Public repository (cause it's free)

*Generate a token

Go to profile

Settings

Developer options

Personal access token

Classic token

Generate a token

Copy this token and save somewhere, if needed then can access easily

Install git in linux

~\$sudo apt update

~\$sudo apt install -y git (If not installed but mainly it is installed)

Make a directory (Project name)

~\$mkdir Dirname

~\$cd Dirname

Add repository

~\$git remote add origin<GitHub URL>

Then Initialise the repository for writing the code

~\$git init

Make a new branch and switch on it

~\$git checkout -b "main"

Then make a file and write the code

~\$vi [main.py](#)

Press i and write the code

Then press esc and :wq! To forcefully save and quit

Add code to staging area

~\$git add . (. Indicates current directory if want to add only file then filename)

Configure your server to the GitHub

~\$git config --global [user.name](#) "username of GitHub"

~\$git config --global [user.email](#) "GitHub email"

Commit the code

~\$ git commit -m "commit message"

Push the code to repository

~\$ git push origin main

Enter the username and personal access token as password

Your code is pushed to GitHub

Go to GitHub and check if there is a pull request if not then it is already merged (If first time)

Git :-

It is a version control tool

It creates three compartments/boxes after git init command

1)Working space

It is where you work

2) Staging area

It is a virtual place where all the tracked and untracked files are present

#Untracked files are those files which are not in staging area

Tracked files are those files which are in staging area

3) Local repo

This is where you commit changes

And then push the code to GitHub

GitHub:-

It is distributed version control system

And it is the cloud based space where all the repositories are present
