

Old methodology of CI/CD

Before DevOps was invented people used to do things manually. This was too frustrating that you have to check the server repeatedly if there is any problem . If there was a problem you have to solve it. First developer wrote code and then pushed to github . Then the engineer (In eg. agile) clones that github code to a new aws instance .

He installs maven as a build tool to build the package. Then locates the pom.xml file present in the project directory. Then he runs mvn clean package and he builds the package and there will be only one package from the following packages

. 1) .jar 2) .war 3) .ear

.jar is a stationary application that can be deployed directly through terminal .

.war is a web application

.ear I don't have much idea about it

Now the engineer makes a new instance/server and install Tomcat in the server. Then he copies the .war package because this is a web application in the webapps directory of tomcat server .

Then we could access the server from chrome by copying the public ip address of the tomcat server and searching https://public ip :8080/webapps if the tomcat is configured correctly .
